ABSTRACT

With more and more materials used in the Selective Laser Sintering (SLS) process, it is becoming necessary to use a database to manage the process efficiently. In this paper, a relational database for the SLS process is described. The database includes powdered material data, sintering parameters, machine characteristics, mechanical properties and surface quality of prototypes. Use of this database will make it easy to store and retrieve processing information and make decisions for planning the SLS. This paper will go on to describe how the database can be extended to include other RP technologies.

Keywords: Rapid Prototyping (RP), Selective Laser Sintering (SLS), Database Management Systems (DBMS), Process Planning.

INTRODUCTION

With the rapid development of modern science, computer technology plays a more and more important role in manufacturing engineering. Many advanced technologies such as computer-aided design/computer-aided manufacturing (CAD/CAM), computer integrated manufacturing (CIM), robotics, concurrent engineering (CE), and flexible manufacturing systems (FMS) have been applied to manufacturing industry. Time-to-market becomes a key factor to determine the survival of a manufacturing company in the global market. Meanwhile, due to globalization of information technology (IT), CIM is seen as a key competitive strategy for future advanced manufacturing systems in the 21st century.

Being regarded as a major technological breakthrough after NC technology, rapid prototyping (RP) is receiving more and more attention from manufacturers and researchers. Also based on computer technology, RP can produce any complex object in a few hours directly from a computer model without any part-specific tooling or knowledge [1]. Now, a lot of companies are using RP to help speed up their product’s time-to-market.

Selective laser sintering (SLS) is a premier RP process with a wide range of materials that can be fabricated into prototypes for conceptual, functional, and tooling applications. With increasing use in the manufacturing chain, it is becoming necessary to use a database to manage the process efficiently. In this paper, a relational database for management of the SLS process is described. Information elements stored in the database include powdered material data, sintering parameters, machine characteristics, prototype’s mechanical properties and surface quality. Online exploitation of databases can make it easy to store and retrieve processing information and make decisions for planning the use of SLS equipment.
FUNDAMENTALS OF RELATIONAL DATABASE

In the simplest sense, a database is a collection of records and files that are organized for a particular purpose [2]. The basic element in the database is called an entity. There are three kinds of relationships between entities: one-to-one, one-to-many, and many-to-many (Figure 1).

![Figure 1 Three kinds of relationships between entities](image)

Nearly all modern database management systems (DBMS) store and handle information using the relational database management model. The term relational stems from the fact that each record in the database contains information related to a single subject and only that subject. Data concerning two classes of information can be manipulated as a single entity based on related data values. This structure is popular among CIM systems because it is relatively easy to design and modify data structures.

A relational database management system (RDBMS) has three main types of capabilities:

- **Data definition**—to define what data will be stored in the database, the type of data, and how the data is related. In some cases, it is also needed to define how the data should be formatted and how it should be validated.
- **Data manipulation**—to handle the data in many ways such as to select data fields, to filter the data, and to sort it.
- **Data control**—to define who is allowed to read, update, or insert data. In many cases, it is also defined how data can be shared and updated by multiple users.

The relational database management systems can be built with many commercial software packages like Oracle, dBASE, FoxPro, and Access. In our research project, the database management system for the selective laser sintering process has been built with Access97.

Within an Access database, the main objects are tables, queries, forms, reports, macros, and modules [3]:

- **Table**—to store the data for the tasks. It is made up of columns, or fields, each of which contains a specific kind of data, and rows, or records, which collect all the data about a particular object.
- **Query**—to provide a custom view of data from one or more tables. It can be defined to select, update, insert, or delete data. Access stores every query as a Structured Query Language (SQL) command.
- **Form**—designed for data input or display or for control of application execution.
• Report—designed for formatting, calculating, printing, and summarizing selected data.
• Macro—a structured definition of one or more actions to perform in response to a defined event.
• Module—custom procedures using the Visual Basic for Application (VBA) language. It can be called from anywhere in the application, or directly associated with a form or a report to respond to events on the associated form or report.

Figure 2 shows the main objects and their relationships in Access.

**IMPLEMENTATION**

In the SLS process, the main entities are SLS machines, powdered materials, sintered prototypes, and sintering parameters. Some useful data, such as machine vendors, powdered...
material properties, prototype's mechanical properties and surface quality, are related with the above four entities. All entities and their relationships are stored in tables.

**Table and Query Design**

Table design is an important step in building a relational database. It is recommended to design many separated tables for retrieving and storing data more efficiently. Some tables and their relationships in the database are shown in Figure 3 and Figure 4.

**Figure 3 Tables defined in the database**

**Figure 4 Relationships among tables**
Queries provide a custom view of data from one or more tables. In the SLS process, the relationships of machine-to-material, machine-to-application, and material-to-application, belong to the many-to-many relationship. Using queries, it is easy to find useful information from these relationships.

**Forms and Reports**

Forms are designed to view and change data in the database. There are five important forms designed with respect to the four entities: frmMachines, frmMaterials, frmApplications, frmSinteringParameters, and frmPrototypeQualities. The form frmMachines provides the specifications about SLS machines. This also includes two subforms that list materials and applications available for the machine. The form frmMaterials provides specifications about the powdered materials. The form frmApplications provides the description and samples concerning applications. The form frmSinteringParameters provides sintering parameters for materials in sintering machines. The form frmPrototypeQualities provides the prototype’s mechanical properties and surface quality.

Reports are designed to print data as required. Four main reports are built for printing the specifications of machines, specifications of powdered materials, sintering parameters and building profiles, and prototype’s mechanical properties and surface quality.

**Layout of Database**

The layout of the database is shown in Figure 5.

APPLICATIONS

Currently, there are six kinds of selective laser sintering system available in the market from two vendors. More than ten powdered materials can be fabricated as visualization models, functional models, patterns for casting, and patterns for tooling. In the sintering process, a lot of sintering parameters should be set according to powdered materials. Taking the DTM sinterstation 2000 system for example, there are 31 parameters that should be set in warm-up, build, and cool-down stages, and 6 parameters related to scale and beam offset in X, Y, Z. In our previous research [4], it was found that the prototype’s mechanical properties and surface quality are dependent on part orientation, powdered material properties and sintering parameters. This is important since the prototype’s mechanical properties and surface quality are important factors in the design-manufacturing cycle. The database provides a convenient way to view, edit, save and print useful information. It assists the user to select machines, materials, and suitable sintering parameters according to application requirements in the design stage. Another useful application is process planning on the SLS [5].

Figure 6 to Figure 9 demonstrate use of the database.

CONCLUSIONS

A relational database has been developed for management of the selective laser sintering process. Use of the database makes it easy to store and retrieve processing information and make decisions for planning the use of SLS equipment. In addition, the database provides an interface to integrate the SLS process with other manufacturing techniques to form part of a CAPP or CIM system. Indeed, this system is aimed at providing a means for effective technology management.

Further research works should be carried out on extending the database to cover all RP processes, incorporating a knowledge base to form an RP planning system. Although using similar data, organized in a similar way, the data interrogation of such a system and the reports would be quite different.

Data collection is important for supporting the database. Further experimental work is ongoing to collect data on materials and prototypes as part of a ‘fine-tuning’ process. This could also be done with the assistance of other researchers, users and vendors to support this project by providing data concerning their experience in use of the technology.
